# 101 WESTERN BLOTTING TROUBLESHOOTING TIPS

## NO BANDS OBSERVED

| Problems  | Explanation  |
|---|--|
| 1. Incorrect primary antibody                     | Antibody has low to no affinity.   |
| 2. Inactive antibody                              | Perform a dot blot.  |
| 3. Insufficient protein concentration             | Increase the amount of protein and use a positive control.   |
| 4. Poor transfer                                  | Make sure the membrane is activated. Transfer buffer must contain methanol when using nitrocellulose membranes. PVDF membranes must be pre-soaked with methanol. |
| 5. Incomplete Transfer.                           | To ensure the transfer is complete, stain the membrane with India Ink, Amido Black or Ponceau S.   |
| 6. Over Transfer.                                 | Reduce time of transfer or voltage.  |
| 7. Incorrect secondary antibody                   | Confirm host species and IgG type of primary.  |
| 8. Antibodies expired                             | Check that all antibodies are in date.   |
| 9. Incorrect storage of antibodies                | Ensure all antibodies are stored as per manufacturer's instructions.   |
| 10. Suboptimal primary antibody incubation time   | Increase incubation time with the primary antibody.  |
| 11. Incompatible primary and secondary antibody   | Maintain a consistent species in both antibodies.  |
| 12. Insufficient secondary antibody concentration | Increase the concentration of primary/secondary antibody.  |
| 13. Excessive washing                             | Reduce the number and duration of washes.  |
| 14. Incorrect orientation                         | Mark your membrane to ensure correct orientation.  |
| 15. Contaminated wash or incubation buffer.       | Use fresh, sterile buffer.   |
| 16. Insufficient exposure time when imaging.      | Re-image the blot with a longer exposure time.   |

## NO BANDS OBSERVED

| Problems   | Explanation   |
|--|---|
| 17. Incorrect filter settings.                     | Ensure the detection instrument is set to read the correct wavelengths. |
| 18. Reduced efficacy of antibodies due to overuse. | Use fresh primary and secondary antibodies for each experiment.         |
| 19. Absence of protein of interest.                | Run a positive control.   |
| 20. Sodium Azide contamination.                    | Sodium Azide contamination will quench HRP signal.                      |
| 21. Isoelectric point >9.                          | Use a different buffer system with higher pH, e.g. CAPS (pH 10.5).      |

## FAINT BANDS (WEAK SIGNAL)

| Problems                                 | Explanation  |
|--|--|
| 22. Insufficient antibody concentration. | Increase the antibody concentration 2-4 fold higher than starting concentration.   |
| 23. Insufficient protein concentration.  | Increase total protein loaded on the gel.  |
| 24. Suboptimal antibody binding.         | Reduce number of washes. Reduce NaCl concentration in the blotting buffer and in the antibody solution (recommended range = 0.15M - 0.5M). |
| 25. Inactive conjugate.                  | Purchase new reagents or switch to ECL.  |
| 26. Old or weak ECL.                     | Use new ECL reagents.  |

## TOO MANY BANDS

| Problems                                     | Explanation  |
|--|--|
| 27. Non-specific antibody.                   | Ensure the antibody used is specific for the protein of interest.  |
| 28. Proteolytic breakdown                    | Use protease inhibitors to prevent the proteolytic breakdown of the antigen.   |
| 29. Gel overloading.                         | Overloading the gel with too much protein can cause the development of "Ghost bands." Optimise protein concentration.  |
| 30. Insufficient blocking.                   | Extend the blocking time.  |
| 31. Low antigen concentration.               | Consider immunoprecipitating target protein.   |
| 32. Non-specific secondary antibody binding. | Use secondary antibody only control. If bands develop use a different secondary antibody.  |
| 33. Analyte aggregation.                     | Increase DTT concentration.  |
| 34. Analyte degradation.                     | Make fresh samples. Reduce the number of freeze/thaw cycles of the sample. Add protease inhibitors to a sample before it is stored.  |
| 35. Protein degradation.                     | Target protein of interest degraded.   |
| 36. Splice variants.                         | Could lead to the visualisation of multiple bands.   |
| 37. High primary antibody concentration.     | Use a lower concentration of primary antibody.   |
| 38. Protein may form multimers.              | If samples are insufficiently reduced, proteins will form dimers, trimers or multimers due to disulfide bond formation. During sample preparation, boil the sample for longer in Laemmli buffer to prevent this. |
| 39. Cells passaged too many times.           | Use the original non-passaged cell line.   |

## TOO MANY BANDS

| Problems                             | Explanation   |
|--------------------------------------|---|
| 40. Antibodies are not purified.     | Use affinity purified antibodies.   |
| 41. The bands are non-specific.      | Use blocking peptides to differentiate between specific and non-specific bands.   |
| 42. Post translational modification. | Protein sample has multiple modified forms e.g. acetylation, methylation and phosphorylation. Check the literature to see if multiple bands have been reported. |
| 43. Ionic interactions.              | Increase salt concentration of incubation buffers. Include stronger detergent in washing step.  |

## WRONG BAND SIZES

### Bands have lower MW than expected

| Problems  | Explanation  |
|---|--|
| 44. Samples have been digested/degraded.                                  | Use fresh sample. Use lysis buffer with proteinase inhibitors.               |
| 45. Primary antibody detecting splice variants.                           | Identify splice variants for your protein. Try a different primary antibody. |
| 46. Primary antibody binding to a similar epitope on a different protein. | Run negative control to detect proteins that react with your antibody.       |

### Bands have higher MW than expected

| Problems                       | Explanation   |
|--------------------------------|---|
| 47. Protein aggregation.       | Decrease protein concentration. Prepare new sample with fresh loading buffer. |
| 48. Incomplete denaturation.   | Denature protein with urea.   |
| 49. Proteins are glycosylated. | Use enzymatic treatment to strip post-translational modifications.            |

## POOR QUALITY TRANSFER

| Problems                             | Explanation   |
|--------------------------------------|---|
| 50. Membrane choice.                 | Choose either PVDF/nitrocellulose (NC) membranes according to the target protein molecular weight.            |
| 51. Dry membrane.                    | It is important not to let the membrane or filter paper dry out.  |
| 52. Incomplete protein resolution.   | Ensure optimal gel concentration is used for the protein of interest.   |
| 53. Incorrect sample preparation.    | The sample must contain DTT or B-Mercaptoethanol and be heated prior to loading.                              |
| 54. Incorrect assembly of membranes. | PVDF and NC membranes should be oriented on the anode (+) side of the gel.                                    |
| 55. Incorrect transfer time.         | Increasing transfer time can improve protein molecule transfer.   |
| 56. Insufficient power supply.       | Membranes can be placed on either side of the gel in the case that the power supply is incorrectly connected. |

## HIGH BACKGROUND

| Problems                           | Explanation   |
|------------------------------------|---|
| 57. Non-specific antibody binding. | Ensure the correct and most specific primary antibody is used.                        |
| 58. Insufficient blocking.         | Optimise blocking time duration.  |
| 59. Incomplete blocking.           | Optimise choice of blocking buffer. Increase protein concentration in blocking agent. |
| 60. Incompatible blocking agent.   | Compare different blocking buffers.   |
| 61. Incorrect membrane choice.     | Nitrocellulose membranes generally have less background compared to PVDF.             |

# 101 WESTERN BLOTTING TROUBLESHOOTING TIPS

## HIGH BACKGROUND

| Problems   | Explanation   |
|--|---|
| 62. Film overexposed.  | Ensure the correct and most specific primary antibody is used.  |
| 63. Secondary antibody binding to the blocking reagent.                  | Optimise blocking time duration.  |
| 64. Incubation temperature is too high.                                  | Optimise choice of blocking buffer. Increase protein concentration in blocking agent.   |
| 65. Excessive incubation.  | Compare different blocking buffers.   |
| 66. Too much substrate (when using enzyme-conjugated antibody).          | Dilute substrate. Reduce substrate incubation time.   |
| 67. Protein is overloaded.   | Dilute sample concentration or reduce load.   |
| 68. Contamination of membranes, solutions, antibody containers or trays. | Wear clean gloves. Use forceps to handle membranes. Use clean glassware and distilled water to prepare solutions. Run cleaning protocol with cleaning buffer. |
| 69. Non-fat dry milk may contain the target antigen.                     | Substitute with 3% BSA.   |
| 70. Suboptimal antibody concentration.                                   | Optimise antibody concentration.  |
| 71. Insufficient washing.  | Increase the number of washes performed. Increase the concentration of Tween 20 used in wash buffer.  |
| 72. Blot has dried out.  | Cover the membrane in buffer during incubation.   |
| 73. Cross-reactivity of antibody with other proteins.                    | Reduce secondary antibody concentration. Use different blocking agent.  |

## SPOTS OR SMUDGES ON THE GEL

### Black dots or speckled background

| Problems   | Explanation   |
|--|---|
| 74. Blocking reagent has clumped together. The antibodies are binding to it. | Binding will appear as dots. Filter the blocking agent.   |
| 75. Contamination of gel or reagents.  | Use fresh, sterile buffer.  |
| 76. Exposure time is too long.   | Reduce the exposure time.   |
| 77. Insufficient amount of solution during washing or incubation.            | Fully immerse the membrane during antibody incubations and washes.                              |
| 78. Contamination of equipment.  | Ensure the electrophoresis equipment is properly washed. Wash the membrane thoroughly.          |
| 79. Uneven agitation.  | Place on a rocker or shaker to ensure uniform agitations during incubations.                    |
| 80. Secondary antibody aggregation.  | Increase secondary antibody dilution. Spin down antibody aggregates.                            |
| 81. Membrane dried unevenly.   | Thoroughly wet the membrane before starting the protocol. Ensure the membrane does not dry out. |

### White spots or smudges

| Problems                                      | Explanation  |
|---|--|
| 82. Air bubbles trapped against the membrane. | Remove any air bubbles trapped between the membrane and the gel during transfer. |

## BANDS APPEAR VERY LOW

| Problems  | Explanation   |
|---|---|
| 83. The gel has been running for too long.        | Try running the gel for a shorter period of time.                                   |
| 84. Insufficient amount of acrylamide in the gel. | Run lower molecular weight proteins in gels with a higher percentage of acrylamide. |

## BANDS APPEAR VERY HIGH

| Problems  | Explanation   |
|---|---|
| 85. The gel has not been running for long enough. | Try running the gel for a longer period of time.                                    |
| 86. Too much acrylamide in the gel.               | Run higher molecular weight proteins in gels with a lower percentage of acrylamide. |

## DISTORTED BANDS

### Smile/Curve effect on the gel

| Problems                                   | Explanation                                    |
|--|--|
| 87. Voltage was too high during migration. | Check the protocol for the suggested voltage.  |
| 88. Gel was too hot during migration.      | Run the gel at 4° C, on ice or in a cold room. |

### Uneven bands

| Problems                                     | Explanation  |
|--|--|
| 89. Gel has polymerized unevenly.            | Check the gel recipe. Make sure the correct amount of TEMED has been added. Ensure the gel is covered entirely in buffer when setting. |
| 90. Salt concentration varies between wells. | Ensure that the salt concentration is similar across different samples.  |

# 101 WESTERN BLOTTING TROUBLESHOOTING TIPS

## DISTORTED BANDS

### Diffused or Streaked bands

| Problems  | Explanation  |
|---|--|
| 91. Excessive amount of protein on the gel.                                 | Reduce the amount of protein loaded on the gel.  |
| 92. Membrane slipped during transfer.                                       | Avoid moving the gel or membrane during transfer.  |
| 93. Contact between the membrane and the gel is incomplete during transfer. | Use thicker filter paper. Squeeze to remove excess buffer and air bubbles from between the gel and membrane. |

### Blurry bands

| Problems  | Explanation   |
|---|---|
| 94. Voltage for electrophoresis is too high.      | Run gel for longer at a lower voltage.                    |
| 95. Air bubbles trapped between membrane and gel. | Remove air bubbles by squeezing with a sterile glass rod. |
| 96. Incorrect loading buffer composition.         | Mix a new loading buffer.                                 |

## WHITE BANDS (IF USING ECL METHOD)

| Problems                                | Explanation  |
|---|--|
| 97. Antibody concentration is too high. | Dilute the antibody to the optimal concentration.    |
| 98. Generation of excessive signal.     | Reduce the concentration of the protein or antibody. |

## WHITE BANDS (IF USING ECL METHOD)

| <b>Problems</b>                                  | <b>Explanation</b>                                |
|--|---|
| <b>99. Overexposure during visualization.</b>    | Decrease exposure time.                           |
| <b>100. The blot was moved during transfer.</b>  | Avoid moving the membrane or gel during transfer. |
| <b>101. Loading sample was too concentrated.</b> | Reduce the amount of sample loaded.               |
